Introduction: A controlled release coconut hydrogel which releases essential supply of nutrients and energy for up a period of up to two hours was recently developed. The potential ergogenic effect of this gel on endurance exercise performance in a hot-humid condition was examined.

Methods: Ten healthy trained cyclists performed steady state (SS) exercise at 65\% \textit{VO}_{2}\textsubscript{peak} for 45 min followed with a 10 km time-trial (TT) in a hot-humid (HH) condition (32\degree C and 75\% RH). Participants were randomly given a water-based hydrogel (W-Gel) or a coconut-based hydrogel (C-Gel) 30 minutes prior to the start of each trial while maintaining a euhydrated state. Gas exchange (\textit{VO}_{2}), heart rate (HR), rectal (\textit{T}_{re}), mean skin temperature (\textit{T}_{sk}) and psychological measures were recorded at regular interval.

Results: There was no significant difference in TT between C-Gel and W-Gel (12.7±2.6 vs. 13.6±3.8 min; p = 0.153). The steady state exercise data indicated both core and mean skin temperature was not significantly different between C-Gel and W-Gel, respectively (38.9±0.2 vs. 38.8±0.3\degree C; p = 0.127 and 35.69±0.67 vs. 35.47±0.63\degree C; p = 0.607). Heart rate was also not significantly affected between the two trials (155±15 vs. 152±13; p = 0.261). Similarly, ratings of perceived exertion and thermal comfort were not significantly affected (p>0.05).

Conclusions: The current observation indicated that hydrogel provided no ergogenic benefit within ~60 min of exercise in a HH condition. This is consistent with the earlier understanding that ~60 min of exercise performance among well-trained athletes are not compromised when they are euhydrated at the onset of exercise.
